

Position Properties — Made Easy

A visual cheat sheet for static, relative, absolute, fixed and sticky.

1. Position Properties at a Glance

POSITION	WHAT HAPPENS
static	Normal/default position
relative	Moves relative to its original position
absolute	Removed from normal flow and positioned relative to a positioned parent
fixed	Stays fixed relative to the browser window, even while scrolling
sticky	Acts normally, then sticks when you scroll to its top value

2. Easy Way to Remember

STATIC

↓

Normal position

RELATIVE

↓

Move from where it normally is

ABSOLUTE

↓

Position relative to a parent

FIXED

↓

Position relative to the screen

STICKY

↓

Normal → sticks while scrolling

3. ☐ Most Important Concept: Relative vs Absolute

Think of it like this:

A relative parent creates the reference point. An absolute child can then use top / right / bottom / left to position itself inside that parent.

The Code

```
.parent {  
  position: relative;  
}  
  
.child {  
  position: absolute;  
  right: 10px;  
  bottom: 10px;  
}
```

Here, the child is positioned 10px from the parent's right and bottom edges.

Without position: relative on the parent, the absolute child may position itself relative to another ancestor (often the page).
